## What is the Triangle Regional Model?

The Triangle Regional Model (TRM) is a state of the practice regional travel demand model. It uses algorithms to represent the **transportation system** and the daily multi-modal **travel choices** that people make. The TRM is the principal analytical tool used by transportation agencies in our region to develop and evaluate transportation strategies that support the **mobility, accessibility, economic health** and **quality of life** for the Triangle region.

All major roads in the region and all transit services provided by local and regional providers are included. The TRM covers all of Wake, Durham and Orange counties, and portions of Alamance, Chatham, Franklin, Granville, Harnett, Johnston, Nash, and Person counties.

Resulting travel demand captures choices related to the number and types of **trips** people make, the **mode** they use to travel, the choice of **destination**, and the **paths** used to reach that destination.

## What should the TRM be used for?

- ✓ To develop and evaluate transportation strategies at the:
  - ✓ **Regional level:** whole metro
  - ✓ **Subarea level:** county, town, city or predefined district
  - ✓ **Corridor level:** collector, arterial, highway, interstate or transit-only facility
- ✓ To evaluate transportation system project additions (e.g. ridership on new transit service), modifications (e.g. new travel lanes on a roadway) or removal
- ✓ To help answer important transportation and land use questions (e.g. toll, parking, or land use density studies)

## What should the TRM *not* be used for?

- ✗ To evaluate operational level analysis such as:
  - × on-street parking
  - × auxiliary lanes
  - × ramp metering
  - × intersection traffic signal timing
  - × intersection level delay
  - × transit management and operations

## Expectations for Application

- Travel demand models can and should be used to inform **decision making**, spark **conversation** and provide **insight**. One of the biggest strengths of travel models is for scenario planning/analysis and to support **storytelling with data**.
- Model output is only as good as the model input. The model is sensitive to input **demographic data** such as population, households, income, workers, children and jobs, but if that data does not well reflect future **planned changes**, model sensitivity will be limited.

## Planning Topics Covered in the Guidebook

### Equity

*How can we **improve transportation equity** through different land use policies?*

Evaluate changes in accessibility and mobility that result from land use changes specifically designed to support underserved communities.

### Community Health Metrics

*How does non-motorized travel change under **different land use scenarios**?*

Evaluate changes in non-motorized travel resulting from increasing the zonal mix of land uses and/or zonal density for specific clusters of zones.

## ★ Quality of Life

How do different land use patterns, investments in transit, or toll pricing influence **travel choices**, commute times, and time spent traveling in congestion?

Conduct various scenario analyses that consider increased density, increased investments in transit, and various toll policies. Evaluate not just highway and transit assignment metrics, but also investigate changes in accessibility metrics, the spatial distribution of non-motorized trips, the spatial distribution of trips, changes in travel times, changes in mode shift for specific communities, etc.

## Economic Development

What are the benefits of **servicing high employment areas** with improved transit service?

Identify TAZs with high employment (specifically low-wage jobs) and low existing transit ridership/service. Investigate the spatial distribution of trips to these high employment areas. Evaluate changes in ridership resulting from new investments connecting these areas.

## Safety

Are there travel model performance metrics that can inform **patterns of high crash locations**?

Use GIS to spatially investigate patterns between highway performance measures such as delay or congestion and high-frequency crash locations. Use this information as a surrogate for identifying possible future concerns in order to inform safety planning.

## Freight

What is the effect of **clustering freight efficient land uses** on travel demand for commercial vehicle (CV) and trucks?

How do these changes influence highway performance measures? Create a land use scenario that clusters freight efficient land uses and evaluate changes in the spatial patterns of CV and truck trips, changes in link level CV and truck demand, and changes in key highway performance measures.

## Land Use

What is the sensitivity of travel choice to **future year growth and land use policies** forecast by local governments that show no change in demographics versus intentionally changing demographics to reflect expected changes?

Evaluate various model performance measures, in particular changes in the spatial distribution of trip productions by trip purpose, non-motorized travel, and modal shifts that result in changing key demographic inputs such as income, percent workers, and percent seniors.

## Non-motorized Modes

How does **removing barriers to access** improve non-motorized trips?

Identify barriers between TAZs with complimentary land uses, e.g. lack of connectivity between retail and residential development, and provide off-road connectors to evaluate changes in non-motorized trips. Or, use forecast link travel demand to identify roadways with low modeled volumes that can act as connectors for cyclists.

## Accessibility

How can **access to jobs** be improved through multimodal transportation investments?

Calculate the difference in number of people or jobs within different travel bands by different modes of travel.

## Mobility

How do different land use policies and/or transportation investments support **increased mobility**? What does this look like for **Communities of Concern**?

Perform analysis using different land use and transportation investment scenarios. Evaluate not just highway and transit assignment metrics, but also investigate changes in accessibility metrics, the spatial distribution of non-motorized trips, the spatial distribution of trips, changes in mode shift for specific communities, etc.

## Glossary

- A Glossary of modeling terms is included in the Guidebook.
